# Methodology and sample profile

# Methodology: Atlas RDR

**Atlas Random Digital Recruitment [RDR]** is a methodology developed by AtlasIntel to calibrate robust samples, representative of the target population.

The method seeks to address sources of bias and possible over-or underrepresentation of specific demographic groups.

**Respondents are recruited randomly during routine web browsing** in geolocated territories on any device (smartphones, tablets, laptops or PCs).

Compared to face-to-face surveys, **RDR avoids the possible psychological impact of human interaction on the respondent at the time of the interview**: the respondent can answer the questionnaire under conditions of full anonymity, without fear of causing a negative impression to the interviewer or to people who may eventually be listening to the answers shared during the interview.

Compared to telephone surveys based on Random Digit Dialing (RDD), **the RDR method allows for granular mapping of non-response patterns**, so that biases arising from variable non-response rates can be adequately addressed during the process of building each sample.

To ensure representativeness at the national level, the AtlasIntel samples are post-stratified using an iterative algorithm on a minimum set of target variables: gender, age group, education level, income level, region, and previous electoral behavior. The samples resulting from the post-stratification process match the profile of the US adult population and that of likely voters.
